Rapid breath-holding in human fetuses at high altitude. Previous physiological studies have shown that the rate of fetal breathing increases with elevation in the monkey and human fetus. If, as is suggested by the geologic history of the developing world, the human fetus was born and grew up in high altitudes, it might exhibit a high frequency of breathing at high elevations. To test this hypothesis, a separate group of 10 fetuses ranging in size from 22 to 33 weeks of gestation (mean 28 weeks) underwent echocardiographic studies at low (2,000 meters), moderate (4,000 meters), and high elevations (5,540 meters) in Tibet. There was a 1.5-fold increase in the rate of fetal breathing with increasing altitude in all fetuses (p less than 0.001). The observed rapid increase in fetal breathing from moderately to high altitudes correlated with the increase in oxygen pressure. These results suggest that rapid breathing in the human fetus is an adaptation to hypoxia at high elevations.Prognostic impact of the Ki-67 index in Ewing's sarcoma. Ewing's sarcoma (EWS) is the second most frequent primary bone malignancy in children. Although survival has improved with the advent of aggressive combined chemoradiation therapy, approximately 20% of patients experience recurrence and ultimately die of the disease. A recently identified key element in prognosis assessment is the assessment of proliferation through the measurement of the Ki-67 index of the tumour cell nuclei. Knowledge of this immunohistochemistry score in EWS could impact on the decision to initiate and modify treatment. EWS cases were retrieved from the database of the European Paediatric Soft Tissue Sarcoma Group. All patients had adequate tissue samples available for immunohistochemistry. Tumours were classified according to the EWES-99 consensus criteria. An immunohistochemical antibody against Ki-67 was performed. The Ki-67 index was determined in more than 150 neoplastic nuclei per case. Statistical analysis was performed using the Spearman

Free topological study of energy landscapes of single molecules: using aromaticity and the Pi-Pi stacking to discriminate non-covalent interactions. We present a topological and symmetry-based algorithm to characterize the energy landscapes of isolated molecules. Our method is based on the analysis of the energy-independent connectivity properties of the molecule's structure. We have used this method to study the non-covalent interaction between the isolated molecule and two different substrates: Au(111) and a molecule more representative of the thermal environment. We

have found that the energy landscape of the surface-reconstructed molecule is topologically similar to that of the molecule in the gas phase, while the energy landscape of the substrate is topologically different, pointing to a more fluid interaction with the surface. On the basis of the representation of the molecule as a 2D-grid with the atoms as nodes and the non-covalent interactions as edges, we also found a role for the molecule's symmetry in its interaction with the substrate, which becomes weaker as symmetry is lost. A higher aromatic character of the molecule results in the development of a greater connectivity network, while distortions (e.g., H-bonded pairs) create local holes in the structure.Monday, October 25, 2012 The Great Los Angeles Airport Air Show (Gala Air) is an annual non-competitive air show held in the Los Angeles area. It is the 3rd largest air show in the U.S., after the Experimental Aircraft Association and the AirVenture in Oshkosh. It is held at the Los Angeles International Airport and the runways are closed to traffic. There is a free shuttle from the adjacent terminals. The show is held in the fall, in September and October. In prior years, the event was held the first week in September, at the end of the season. Starting in 2013, the event is held in the second week of October. The show includes fly-bys from the 48 US Air Force squadrons based at March Air Force Base. Fly-bys from NASA.
